Abstract

Objective

To examine the association between peripheral blood lymphocyte pharmacodynamics and autoimmune adverse events (AEs) or return of disease activity in alemtuzumab-treated patients with relapsing-remitting MS.

Methods

Patients received 2 alemtuzumab courses (12 mg/d IV; 5 days at baseline, 3 days 12 months later) in the 2-year Comparison of Alemtuzumab and Rebif Efficacy in Multiple Sclerosis studies (NCT00530348 and NCT00548405) and could then receive as-needed alemtuzumab or other disease-modifying therapy in a 4-year extension (NCT00930553). Lymphocytes were phenotyped quarterly over 2 years using fluorescence-activated cell sorting. Pharmacodynamic assessments included counts of total lymphocytes, CD3⁺ T cells, CD4⁺/CD8⁺ T cells (total/naive/memory/regulatory [T_{reg}]), and CD19⁺ B cells (total/immature/mature/memory) and ratios of CD19⁺ (total/immature/mature/memory) to T_{reg} (CD4⁺/CD8⁺) counts. Assessed autoimmune AEs included immune thrombocytopenia, nephropathies, and thyroid events. Efficacy assessments included relapses, 6-month confirmed disability worsening (CDW), and MRI disease activity.

Results

Lymphocyte repopulation patterns, including ratios between distinct lymphocyte subsets (e.g., CD19⁺ to T_{reg} cell count ratios), showed no significant differences over 2 years in patients developing/not developing autoimmune AEs, relapses, CDW, or MRI activity through 6 years following alemtuzumab. Lymphocyte kinetics were also unrelated to multiple autoimmune AEs or extreme clinical phenotypes.

Conclusions

Repopulation kinetics of the evaluated peripheral lymphocyte subsets did not predict autoimmune AE occurrence or disease activity, including return of disease activity after 2 alemtuzumab courses. Further study is needed to investigate potential antigen-level markers of treatment response.

Glossary

AE = adverse event; **B_{reg}** = regulatory B; **CARE-MS** = Comparison of Alemtuzumab and Rebif Efficacy in Multiple Sclerosis; **CDW** = confirmed disability worsening; **EDSS** = Expanded Disability Status Scale; **MMRM** = mixed-effects model for repeated measures; **NEDA** = no evidence of disease activity; **RRMS** = relapsing-remitting MS; **T_{reg}** = regulatory T.

Alemtuzumab is a humanized monoclonal antibody that selectively depletes circulating CD52-expressing B and T lymphocytes.^{1,2} Following depletion, a distinctive pattern of lymphocyte repopulation potentially leads to a rebalanced immune system.^{3–5}

In phase III trials, patients with relapsing-remitting MS (RRMS) receiving alemtuzumab experienced significant clinical and MRI efficacy improvements vs subcutaneous interferon beta-1a over 2 years.^{6,7} Efficacy was maintained over 5 additional years in 2 extension studies.^{8–14} The most frequent adverse events (AEs) with alemtuzumab were infusion-associated reactions; autoimmune AEs also occurred, including thyroid events, immune thrombocytopenia, and nephropathies.^{6–13,15}

Pharmacodynamic changes after lymphocyte depletion, including different repopulation patterns among cell subsets, may account for the overall efficacy of alemtuzumab in RRMS and its associated AE profile.^{1,16–18} Furthermore, differences among patients' lymphocyte repopulation patterns have been hypothesized to explain individual differences in drug response and create the environment for autoimmune AEs in some patients.¹⁹ This may include establishment of permanent vs more transient influences on tolerance-associated immune regulatory network dynamics.²⁰

However, biomarkers that would predict response to alemtuzumab or selection of patients at risk for development of autoimmune events have not been identified.²¹ Although increased serum interleukin-21 levels before alemtuzumab have been associated with autoimmune disorders posttreatment, the widespread applicability of such an assay has not been established.²² Furthermore, no biomarkers exist for predicting recurrence of disease activity after 2 alemtuzumab courses. The current post hoc analysis methodically assesses whether pharmacodynamic patterns of major peripheral blood lymphocyte populations are associated with autoimmune AEs or MS disease activity over 6 years after initiating alemtuzumab.

Methods

Design of CARE-MS and extension studies of alemtuzumab

The efficacy and safety of alemtuzumab were established in 2 phase III studies against subcutaneous interferon beta-1a in patients with active RRMS who were either treatment naive (Comparison of Alemtuzumab and Rebif Efficacy in Multiple Sclerosis [CARE-MS] I; ClinicalTrials.gov trial identifier: NCT00530348; aged 18–50 years) or had an inadequate

response to previous therapy (CARE-MS II; NCT00548405; aged 18–55 years).^{6,7} In the 2-year CARE-MS studies (conducted at 178 academic medical centers or clinical practices in 23 countries; starting in September 2007), patients in the alemtuzumab arm received 2 courses of alemtuzumab 12 mg/d IV on 5 consecutive days at baseline and on 3 consecutive days 12 months later.^{6,7} Patients who completed the phase III studies could enter the 4-year CARE-MS extension (CAMMS03409; NCT00930553), in which they could receive additional courses of alemtuzumab (12 mg/d on 3 consecutive days ≥12 months after the most recent dose) as needed for relapse or MRI activity or receive other licensed disease-modifying therapy at the investigator's discretion.^{10,11} Patients completing the CARE-MS extension study could enroll in an additional extension, the 5-year long-Term follow-up study for multiple sclerosis Patients who have completed the Alemtuzumab extension (TOPAZ) study (NCT02255656), in which further evaluation is ongoing.^{8,9,12,13}

Post hoc analysis

Two-year lymphocyte pharmacodynamics were assessed in alemtuzumab-treated patients (N = 802), stratified by whether they experienced autoimmune AEs, relapse, 6-month confirmed disability worsening (CDW), or MRI disease activity at any time point within 6 years of follow-up.

Autoimmune AEs were defined as any of the following, documented at any point within 6 years of follow-up: thyroid AEs (excluding asymptomatic abnormal laboratory investigations), immune thrombocytopenia (defined according to diagnostic criteria outlined by an international working group²³), or autoimmune nephropathy (in particular, anti-glomerular basement membrane disease or membranous glomerulonephropathy). Monitoring for autoimmune AEs (as part of the safety monitoring program) included quarterly thyroid function tests, monthly hematology tests for immune thrombocytopenia, and monthly serum creatinine tests and urinalysis with microscopy for nephropathy, as well as spontaneous reporting of AEs and serious AEs. Education on signs and symptoms of autoimmune AEs was provided to health care providers and patients. All monitoring began at baseline and continued until 4 years after the last alemtuzumab administration, or until study end, whichever occurred later. The 4-year monitoring period restarted if patients received additional courses of alemtuzumab. Treatment for autoimmune AEs was at the discretion of the treating neurologist in consultation with local endocrinologists, hematologists, or nephrologists.

Relapses were defined as new neurologic symptoms attributable to MS lasting ≥48 hours with an objective change in

neurologic examination. Six-month CDW was defined as an increase of ≥ 1.0 Expanded Disability Status Scale (EDSS) point (or ≥ 1.5 points if the baseline EDSS score = 0), confirmed over 6 months. The EDSS score was assessed quarterly and at the time of suspected relapse by raters who were blinded throughout the follow-up period to core study treatment assignment and treatment history. MRI disease activity was defined as new gadolinium-enhancing T1 lesions on current MRI or new/enlarging T2 hyperintense lesions since last MRI. MRI was assessed annually by imaging specialists blinded to core study treatment assignment and treatment history. If patients experienced autoimmune events, relapse, CDW, or MRI disease activity at any time during the follow-up period, they were classified as having had that type of event from month 0 onward.

In support of the primary analyses, additional analyses assessed lymphocyte pharmacodynamics in patients with multiple autoimmune AEs and patients with various “extreme efficacy” phenotypes, including patients with or without sustained “no evidence of disease activity” (NEDA; absence of relapse, CDW, and MRI disease activity, sustained over years 0–6); with or without both relapse and CDW (clinical NEDA); with or without both severe relapse and CDW; and with CDW, 6-month confirmed disability improvement (≥ 1.0 -point EDSS score decrease from baseline [assessed in patients with baseline EDSS score ≥ 2.0]), or stable EDSS score.

Lymphocyte dynamics

Blood cell counts in the CARE-MS studies were performed monthly. Lymphocytes were phenotyped using fluorescence-activated cell sorting (Quest Diagnostics; Exton, PA) at baseline and quarterly thereafter, as well as at months 1 and 13 (i.e., 1 month after receiving alemtuzumab courses 1 and 2, respectively). Peripheral blood mononuclear cells were stained using a T-cell panel of monoclonal antibodies against CD45RA-FITC (clone L48), CD27-PE (clone L128), CD3-PerCP-Cy5.5 (clone SK7), CD25-PE-Cy7 (clone 2A3), CD127-APC (clone 40131), and CD4-APC-Cy7 (clone SK3), and a B-cell panel of monoclonal antibodies against CD27-FITC (clone L128), IgD-PE (clone IA6-2), CD19-PerCP-Cy5.5 (clone SJ25C1), CD10-PE-Cy7 (clone HI10a), CD38-APC (clone HB7), and CD69-APC-Cy7 (clone FN50) (all antibodies from BD Biosciences; San Jose/San Diego, CA [except CD127-APC: from R&D Systems; Minneapolis, MN]). Lymphocyte data from the CARE-MS I and II studies were pooled for analysis. Absolute cell counts were analyzed for total levels of lymphocytes; all CD3⁺ T lymphocytes, CD4⁺ T lymphocytes, and CD8⁺ T lymphocytes; and CD19⁺ B lymphocytes.

A lymphocyte substudy was conducted at select study centers, in which additional lymphocyte phenotype analyses were performed for the naive, memory, and regulatory (T_{reg}) subsets of CD4⁺ and CD8⁺ T lymphocytes and the immature, mature, and memory subsets of CD19⁺ B lymphocytes (n = 146). The phenotypes of all cell subsets assessed are

defined in the table. To control for any effect of changes in T_{reg} cell levels over time, the kinetic profiles of CD19⁺ B cells (total, immature, mature, and memory) were also assessed relative to CD4⁺ and CD8⁺ T_{reg} cell counts.

Statistical analyses

All data were analyzed by alemtuzumab treatment course. Patients were categorized as “active” or “nonactive” based on defined events: presence or absence of autoimmune AEs, relapses, CDW, and MRI disease activity. To compare the depletion at month 1 and month 13, and the differential reconstitution between groups, linear mixed-effects models for repeated measures (MMRMs) were undertaken with lymphocyte parameters as the outcome variable. Explanatory variables included age and baseline value and either autoimmune AEs, relapse, CDW, or MRI disease activity. Separate MMRMs were fit for separate events as explanatory variables. Multiple hypothesis testing was adjusted using the Bonferroni correction and the Benjamini-Hochberg procedure.²⁴

Standard protocol approvals, registrations, and patient consents

The CARE-MS trials and CAMMS03409 extension are registered with ClinicalTrials.gov (NCT00530348, NCT00548405, and NCT00930553). All procedures were approved by the institutional ethics review boards of participating sites. Patients provided written informed consent.

Data availability

Qualified researchers may request access to patient-level data and related study documents including the clinical study report, study protocol with any amendments, blank case report form, statistical analysis plan, and data set specifications. Patient-level data will be anonymized and study documents will be redacted to protect the privacy of trial participants. Further details on Sanofi’s data-sharing criteria, eligible studies, and process for requesting access can be found at clinicalstudydatarequest.com.

Table Lymphocyte subset phenotypes

Lymphocyte designation	Lymphocyte subset name	Phenotype
Naive CD4⁺ T cells	Naive CD3 ⁺ 4 ⁺ T cells	CD4 ⁺ 45RA ⁺ 27 ⁺
Memory CD4⁺ T cells	Memory CD3 ⁺ 4 ⁺ T cells	CD4 ⁺ 45RA ⁻
CD4⁺ T_{reg} cells	CD3 ⁺ 4 ⁺ regulatory T cells	CD4 ⁺ 25 ^{int/br+} 127 ^{lo/-}
Naive CD8⁺ T cells	Naive CD3 ⁺ 8 ⁺ T cells	CD8 ⁺ 45RA ⁺ 27 ⁺
Memory CD8⁺ T cells	Memory CD3 ⁺ 8 ⁺ T cells	CD8 ⁺ 45RA ⁻
CD8⁺ T_{reg} cells	CD3 ⁺ 8 ⁺ regulatory T cells	CD8 ⁺ 25 ^{int/br+} 127 ^{lo/-}
Immature B cells	Immature B cells	IgD ⁺ CD19 ⁺ 27 ⁺ 38 ⁺ 10 ⁺
Mature B cells	Mature naive B cells	IgD ⁺ CD19 ⁺ 27 ⁺ 38 ⁺ 10 ⁻
Memory B cells	Memory B cells	CD19 ⁺ 27 ⁺

Abbreviation: T_{reg} = regulatory T.

Results

Patients and overall lymphocyte profiles

A total of 811 patients were treated with alemtuzumab 12 mg in CARE-MS I and II; baseline characteristics were reported previously (mean age 34.0 [SD 8.24] years).^{6,7} Total lymphocyte, CD4⁺ and CD8⁺ T-lymphocyte, and CD19⁺ B-lymphocyte counts following alemtuzumab treatment were assessed in 802 patients (figure 1).

CD4⁺, CD8⁺, and CD19⁺ lymphocyte depletion and repopulation patterns over 2 years are not associated with risk of an autoimmune event over 6 years

Of the 802 patients, 447 (56%) developed autoimmune AEs by definition. There was no significant overall difference in depletion or repopulation patterns of total lymphocytes, CD4⁺ and CD8⁺ T lymphocytes, or CD19⁺ B lymphocytes (assessed over 2 years) in patients who did or did not experience autoimmune AEs over 6 years (figure 2). The timing and magnitude of the changes in total T- and B-lymphocyte levels after treatment, as well as the repopulation patterns, were comparable between patients with or without autoimmune AEs (figure 2). Results for CD3⁺ T-lymphocyte counts were similar between the subgroups (figure e-1, links.lww.com/NXI/A160).

CD4⁺, CD8⁺, and CD19⁺ lymphocyte depletion and repopulation patterns over 2 years are not associated with clinical and MRI efficacy parameters over 6 years

Total lymphocyte, CD4⁺ and CD8⁺ T-lymphocyte, and CD19⁺ B-lymphocyte depletion and repopulation patterns were also similar in patients who did or did not experience relapses, CDW, or MRI disease activity through 6 years following alemtuzumab treatment (figure 3, A–C). Among the various efficacy subgroups, the timing and magnitude of the changes in total CD4⁺ and CD8⁺ T- and CD19⁺ B-lymphocyte levels after treatment, as well as the repopulation pattern, were comparable (figure 3, A–C). Results for CD3⁺ T-lymphocyte counts were similar (figure e-1, links.lww.com/NXI/A160).

Analysis of repopulation of specific lymphocyte subsets did not show association with the risk of an autoimmune event or disease activity over 6 years

In the expanded phenotype analysis of CD4⁺ and CD8⁺ T-lymphocyte subsets (naïve, memory, and T_{reg} cells) and CD19⁺ B-lymphocyte subsets (immature, mature, and memory cells) in a subpopulation of patients (n = 146), repopulation kinetics over 2 years did not differ overall in patients with or without autoimmune AEs, relapses, CDW, or MRI disease activity through 6 years (figure 4, A–C).

Figure 1 Median lymphocyte counts in patients treated with alemtuzumab 12 mg

Median total lymphocyte, CD4⁺ and CD8⁺ T-lymphocyte, and CD19⁺ B-lymphocyte counts in the overall pooled Comparison of Alemtuzumab and Rebif Efficacy in Multiple Sclerosis population treated with alemtuzumab 12 mg. N value range over 24 months: 752–802 patients. Vertical lines indicate administration of alemtuzumab. Dashed horizontal lines represent LLN for each of the lymphocyte subsets presented. IQR = interquartile range; LLN = lower limit of normal.

Figure 2 Median lymphocyte counts in alemtuzumab-treated patients with or without autoimmune AEs

(A) Median total lymphocyte, (B) CD4⁺ and (C) CD8⁺ T-lymphocyte, and (D) CD19⁺ B-lymphocyte counts in patients from the pooled Comparison of Alemtuzumab and Rebif Efficacy in Multiple Sclerosis trials treated with alemtuzumab 12 mg, stratified by the presence or absence of autoimmune events. N value range over 24 months: 415–447 patients without autoimmune AEs; 337–355 patients with autoimmune AEs. Vertical lines indicate administration of alemtuzumab. AE = adverse event; IQR = interquartile range; LLN = lower limit of normal.

For both the autoimmune AE and efficacy assessments, the key pharmacodynamic characteristics of the lymphocyte subsets following alemtuzumab treatment were comparable regardless of autoimmune event or efficacy status. Absolute counts of CD4⁺ and CD8⁺ T-lymphocyte subsets (naïve, memory, and T_{reg} cells) were typically lowest at the time of first

posttreatment blood count (month 1) and reconstituted steadily after each treatment course (figure 4, A and B). CD8⁺ T_{reg} cells showed less pronounced depletion compared with CD4⁺ T_{reg} cells (figure 4, A and B). Absolute counts of mature and memory CD19⁺ B lymphocytes decreased posttreatment and were lowest at month 1, whereas absolute counts of

Figure 3 Median lymphocyte counts in alemtuzumab-treated patients with or without disease activity

Median total lymphocyte, CD4⁺ and CD8⁺ T-lymphocyte, and CD19⁺ B-lymphocyte counts in Comparison of Alemtuzumab and Rebif Efficacy in Multiple Sclerosis patients treated with alemtuzumab 12 mg, stratified by the presence or absence of (A) relapse, (B) 6-month CDW, and (C) MRI disease activity. N value range over 24 months: 356–388 patients without relapse; 395–414 patients with relapse; 567–606 patients without CDW; 184–196 patients with CDW; 263–280 patients without MRI activity; 485–516 patients with MRI activity. Vertical lines indicate administration of alemtuzumab. CDW = confirmed disability worsening; IQR = interquartile range; LLN = lower limit of normal.

immature B lymphocytes increased posttreatment and were highest at month 3 (figure 4C). Mature B cells repopulated to approach baseline levels by month 6, followed by a rise above baseline levels; memory B cells repopulated more slowly (figure 4C).

In light of a recently put forward hypothesis that variations in the efficacy and safety of alemtuzumab may reflect B-cell hyper-repopulation in the absence of effective T-cell regulation in some patients,¹⁹ we additionally visualized our data in an alternative manner, by normalizing the kinetic profiles of B cells against CD4⁺ and CD8⁺ T_{reg} cell levels. No differences in depletion or repopulation kinetics were seen in patients with or without autoimmune events, relapse, CDW, or MRI activity through 6 years (figure e-2, A and B, links.lww.com/NXI/A161).

Additional analyses in patients with or without multiple autoimmune AEs or “extreme efficacy” phenotypes (e.g., with or without sustained NEDA) also failed to find any significant overall differences in depletion or repopulation profiles (data not shown). Of note, our analysis did not reveal a specific lymphocyte pattern in the first 2 years that would allow a prediction of the return of disease activity after the second course of alemtuzumab.

Discussion

B and T lymphocytes play an integral role in the disease process in MS.²⁵ By selectively depleting B and T lymphocytes, alemtuzumab induces a lymphopenia that is measurable in the peripheral blood. The distinct repopulation patterns of B and T subsets following alemtuzumab

Figure 4 Lymphocyte subset counts in alemtuzumab-treated patients with or without autoimmune AEs or disease activity

(A) CD4⁺ T-, (B) CD8⁺ T-, and (C) CD19⁺ B-lymphocyte subset counts in Comparison of Alemtuzumab and Rebif Efficacy in Multiple Sclerosis patients treated with alemtuzumab 12 mg, stratified by the presence or absence of autoimmune AEs, relapse, 6-month CDW, and MRI disease activity. N value range over 24 months: 29–72 patients without autoimmune AEs; 30–76 patients with autoimmune AEs; 23–72 patients without relapse; 27–75 patients with relapse; 44–108 patients without CDW; 14–38 patients with CDW; 23–63 patients without MRI activity; 35–84 patients with MRI activity. AE = adverse event; CDW = confirmed disability worsening; IQR = interquartile range; T_{reg} = regulatory T.

treatment, which have been described previously,^{26,27} lead to quantitative and qualitative changes in immune regulatory networks. These changes include suppression of memory B cells, which may play several roles in the pathogenesis of

MS,^{28,29} a relative increase in T_{reg} and memory T-cell counts, and a potential shift from a pro- to anti-inflammatory environment (driven by differential reconstitution of T-cell subsets).^{26,27,30,31} Despite this knowledge, few studies have

attempted to correlate aspects of these pharmacodynamic changes with either safety or efficacy or the need for additional courses of alemtuzumab.

The present study assessed lymphocyte dynamics over the first 2 years following alemtuzumab initiation in relation to the development of autoimmune events or the return of disease activity over 6 years. This enabled a methodical evaluation of the prognostic value of lymphocyte depletion and repopulation patterns, specifically focusing on the putatively most important populations ($CD4^+/CD8^+$ T cells and $CD19^+$ B cells), including key subsets such as T_{reg} cells. The questions addressed were whether differences in the depletion or repopulation patterns of these cell types are associated with (1) development of autoimmune AEs or (2) efficacy (including the relevant question of the need for retreatment). In answer to the first question, our analysis demonstrated the repopulation kinetics of the tested lymphocyte populations did not differ in alemtuzumab-treated patients with or without autoimmune AEs over 6 years. Our findings are consistent with a previous study demonstrating that T-cell regulation does not play a role in the development of autoimmunity in alemtuzumab-treated patients; instead, the autoimmunity may be largely driven by reduced thymopoiesis, a restricted T-cell repertoire, and homeostatic expansion of T cells that have escaped depletion.³² This is also in line with a study by Jones et al.³³, which suggested that increased levels of interleukin-21 may drive cycles of T-cell expansion and apoptosis after alemtuzumab, thus increasing the opportunities for T cells to encounter self-antigen that leads to autoimmune AEs.

Importantly, our study could not confirm what one of the prevailing hypotheses in this area of research would suggest: namely, that an overshoot of B cells is a likely contributor to the risk of disease exacerbation and/or autoimmune de-regulation. That hypothesis is based on the observation that after initial depletion with alemtuzumab treatment, B cells in many patients begin to repopulate to levels exceeding those observed before treatment, with implications for safety based on B-cell hyper-repopulation in the absence of effective T-cell regulation.¹⁹ The results from our analysis demonstrated that the repopulation kinetics of B cells, including memory B cells, did not differ in alemtuzumab-treated patients with or without autoimmune AEs over 6 years. Furthermore, there were no differences either in the B to T_{reg} cell ratios or the repopulation patterns of T-cell subsets between patients with or without autoimmune AEs.

Our study also provides evidence that more robust or accelerated lymphocyte repopulation does not predict the return of clinical or MRI disease activity in alemtuzumab-treated patients over 6 years. These findings extend those from a previous analysis that examined the relationship between lymphocyte pharmacodynamics and clinical efficacy over the course of the CARE-MS core (2-year) studies. In that analysis, median cell counts for total lymphocytes,

T lymphocytes ($CD3^+$, $CD4^+$, and $CD8^+$), and $CD19^+$ B lymphocytes were similar at months 1 and 13 in patient subgroups stratified by whether they experienced a relapse or CDW event subsequent to the time point being assessed. The rate of lymphocyte repopulation was also similar between patients who did or did not experience a relapse or CDW after receiving alemtuzumab.³⁴

The findings of this study imply that the pharmacodynamic patterns of major lymphocyte populations in the peripheral blood within the 2 years following alemtuzumab initiation do not have prognostic value. Peripheral immune phenotyping may be too superficial or not sufficiently sensitive to detect differences among individuals in immune regulatory and tolerance networks that likely occur after alemtuzumab treatment. Of particular interest, a recent study of patients with MS demonstrated that some self-antigens that are expressed on peripheral B memory cells are also expressed in the brain, and T cells that become autoreactive to the antigen can also migrate to brain MS lesions.³⁵ Further research on the effects of alemtuzumab at the antigen-specific level and within the CNS will likely provide additional insights into its overall mechanism of action and underlying mechanisms of autoimmune AEs, clinical response, and potential prognosis.

Limitations of our study include the caveats that are inherent in any post hoc analysis. In addition, the lymphocyte data in this study only extend for the first 2 years after initiation of alemtuzumab treatment; longer-term follow-up may have provided additional insights. As the depth of immune phenotyping in our study was limited, the pharmacodynamics of other leukocyte subsets that are linked to response to alemtuzumab (i.e., natural killer cells, dendritic cells, and regulatory B [B_{reg}] cells) need to be further investigated. For example, relative increases in $CD56^{bright}$ natural killer cells^{36,37} and B_{reg} cells have been reported following initiation of alemtuzumab, along with decreased proportions of dendritic cell subsets that are capable of eliciting detrimental immune responses in MS.³⁷ Differences in the pharmacodynamics of these subsets could also underlie autoimmune events or differences in efficacy responses in patients treated with alemtuzumab. Of particular interest in the case of peripheral B_{reg} cells, a recent study showed levels of the $CD19^+CD24^{hi}CD38^{hi}$ cell subset to deplete with the onset of severe relapses and repopulate during recovery, although this observation was based on data from a single alemtuzumab-treated patient.³⁸ Further analysis of the pharmacodynamics of B-cell clones may provide additional insight into autoimmune events in alemtuzumab-treated patients. Finally, in addition to studying peripheral blood, further research on lymphoid organs and the CSF is needed to improve understanding of the interrelation of different compartments contributing to immune regulation after alemtuzumab treatment.

The current analyses suggest that differences in depletion or repopulation kinetics of the major subpopulations of

peripheral blood lymphocytes have no prognostic value in alemtuzumab-treated patients with RRMS. However, repopulation patterns of specific B-cell clones with the potential to express autoimmune antibodies, and the relevance of those patterns to autoimmune AE occurrence, remain to be determined. Lymphocyte repopulation kinetics, at the level in the present analysis, likely cannot be used to predict the need for administration of additional courses of alemtuzumab.

Giancarlo Comi, MD	University Vita-Salute San Raffaele, Milan, Italy	Author	Acquisition and interpretation of the data and critical revision of the manuscript
Guillermo Izquierdo, MD, PhD	Virgen Macarena University Hospital, Seville, Spain	Author	Acquisition and interpretation of the data and critical revision of the manuscript
Ho Jin Kim, MD, PhD	Research Institute and Hospital of National Cancer Center, Goyang, South Korea	Author	Acquisition and interpretation of the data and critical revision of the manuscript
Basil Sharrack, MD, PhD, FRCP, FAAN	NIHR Sheffield Biomedical Research Centre, Sheffield Teaching Hospitals, University of Sheffield, Sheffield, United Kingdom	Author	Acquisition and interpretation of the data and critical revision of the manuscript
Carlo Tornatore, MD	Georgetown University Medical Center, Washington, DC	Author	Acquisition and interpretation of the data and critical revision of the manuscript
Nadia Daizadeh, PhD	Sanofi, Cambridge, MA	Author and statistician	Design and conceptualization of the analysis; analysis of the data; interpretation of the data; and critical revision of the manuscript
Luke Chung, MD, MPH	Sanofi, Cambridge, MA	Author	Design and conceptualization of the analysis; interpretation of the data; and critical revision of the manuscript

Continued

Appendix (continued)

Name	Location	Role	Contribution
Alan K. Jacobs, MD, FAAN	Sanofi, Cambridge, MA	Author	Design and conceptualization of the analysis; interpretation of the data; and critical revision of the manuscript
Richard J. Hogan, PhD	Eloquent Scientific Solutions, Sydney, NSW, Australia	Author	Interpretation of the data and drafted the manuscript for intellectual content
Linda V. Wychowski, PhD	Eloquent Scientific Solutions, Philadelphia, PA	Author	Interpretation of the data and drafted the manuscript for intellectual content
Bart Van Wijmeersch, MD, PhD	Rehabilitation & MS-Centre Overpelt, BIOMED, Hasselt University, Hasselt, Belgium	Author	Acquisition and interpretation of the data and critical revision of the manuscript
